Preface

The way we design and write software to do computation and AI today sucks. How much you ask? Hrm..., let me think..., It's a vat of boiling poop, mixed with pee, slowly swirling and bubbling toward that dehydrated semi-solid state of goop that serves to repel and repulse most normal people, only attracting the few unfortunate-fortunate folks that happen to be tantalized with scat.

Hrm, too much? Probably. I guess you'd expect me to use concrete examples and cite evidence to make my points, with me being a professor and all. I mean, I could write something like *"The imperative programming model utilized in near all of the production software produced in the last four decades has not fundamentally changed since blah blah blah..."* to meet expectations. I'd certainly sound more credible and perhaps super smart. I have indeed grown accustomed to writing that way and boy has it gotten old. Well, I'm not going to do that here. Let's have fun. Afterall, Jaseci has never been work for me, its play. Very ambitious play granted, but play at it's core.

Everything here is based on my opinion...no, *expert* opinion, and my intution. That suffices for me, and I hope it does for you. Even though I have spent many decades coding and leading coders working on the holy grail technical challenges of our time, I won't rely on that to assert my credibility. Let these ideas stand or die on thier own merit. Its my gut that tells me that we can do better. This book describes my attempt at better. I hope you find value in it. If you do, awesome! If you don't, awesome!

Chapter 3

Abstrations of Jaseci

3.1 Graphs, the Friend that Never Gets Invited to the Party

There's something quite strange that has happend with our common languages over the years, ...decades. When you look at it, almost every data structure we programmers use to solve problems can be modeled formally as a graph, or a special case of a graph, (save perhaps hash tables). Think about it, stacks, lists, queues, trees, heaps, and yes, even graphs, can be modeled with graphs. But, low and behold, no common language ustilizes the formal semantics of a graph as its first order abstraction for data or memory. I mean, isn't it a bit odd that practically every data structure covered in the language-agnostic classic foundational work *Introduction to Algorithms* [4] can most naturally be be reasoned about as a graph, yet none of the common languages have built in and be designed around this primitive. I submit that the graph semantic is stupidly rich, very nice for us humans to reason about, and, most importantly for the purpose of Jaseci, is inherently well suited for the conceptualization and reasoning about computational problems, especially AI problems.

There are a few arguments that may pop into mind at this point of my conjecture.

- "Well there are graph libraries in my favorite language that implement graph symantics, why would I need a language to force the concept upon me?" or

- "Duh! Interacting with all data and memory through graphical abstractions will make the language ssllooowww as hell since memory in hardware is essitially a big array, what is this dude talking about!?!?"
(a) Directed graph with cycle between nodes three and four.
(b) Multigraph with parallel edges and self-loops

Figure 3.1: Examples of first order graph symantics supported by Jaseci.[1]

For the former of these two challenges, I counter with two points. First, the core design languages are always based upon their inherent abstractions. With graphs not being one such abstraction, the language's design will not be optimized to empower programmers to nimbly do gymnastics with the rich language symantics that correspond to the rich semantics graphs offer (You'll see what I mean in later chapters). And second, libraries suck (See A.1).

For the latter question, I'd respond, "Have you SEEN the kind of abstractions in modern languages!?!? It's rediculous, lets look at python dictionaries, actually scratch that, lets keep it simple and look at dynamic typing in general. The runtime complexity to support dynamic typing is most certainly hgiher than what would be needed to support graph symantics. Duh right back at'ya!"

3.1.1   Yes, But What Kind of Graphs

There are many categories of graphs to consider when thinking about the abstractions to support in Jaseci. There are rules to be defined as to the availabe semantics of the graphs. Should all graphs be directed graphs, should we allow the creation of undirected graphs, what about parallel edges or multigraph, are those explicitly expressible or discouraged / banned, can we express hypergraph, and what combination of these graphical sematics should be able to be manifested and manipulated through the programming model. At this point I can feel your eyes getting droopy and your mind moving into that intermediary state between concious and sleeping, so let me cut to the answer.

---

[1]Images credits to wiki contributers [2, 3]

In Jaseci, we elect to assume the following semantics:

1. Graphs are directed (as per Figure 3.1a) with a special case of a doubly directed edge type which can be utilized practically as an undirected edge (imagine fusing the two edges between nodes 3 and 4 in the figure).

2. Both nodes and edges have their own distinct identities (i,e. an edge isn't representable as a pairing of two nodes). This point is important as both nodes and edges can have contexts.

3. Multigraphs (i.e., parallel edges) are allowed, including self-loop edges (as per Figure 3.1b).

4. Graphs are not required to be acyclic.

5. No hypergraphs, as I wouldn't want Jaseci programmers heads to explode.

As an aside, I would describe Jaseci graphs as strictly unstrict directed multigraphs that leverages the semantics of parallel edges to create a laymans 'undirected edge' by shorthanding two directed edges pointed in opposite directions between the same two nodes.

Nerd Alert 1 *(time to let your eyes glaze over)*

I'd formally describe a Jaseci Graph as an 7-tuple $(N, E, C, s, t, c_N, c_E)$, where

1. N is the set of nodes in a graph

2. E is the set of edges in a graph

3. C is the set of all contexts

4. s: $E \rightarrow V$, maps the source node to an edge

5. t: $E \rightarrow V$, maps the target node to an edge

6. c_N: $N \rightarrow C$, maps nodes to contexts

7. c_E: $E \rightarrow C$, maps edges to contexts

An undriected edge can then be formed with a pair of edges (x, y) if three conditions are met,

1. $x, y \in E$

2. $s(x) = t(y)$, and $s(y) = t(x)$

3. $c_E(x) = c_E(y)$

If you happend to have read that formal definition and didn't enter deep comatose you may be wondering "Whoa, what was that context stuff that came outta nowhere! What's this guy trying to do here, sneaking a new concept in as if it was already introduced and described."

Worry not friend, lets discuss.

3.1.2   Putting it All Into Context

A key principle of Jaseci is to reshape and reimagine how we view data and memory. We do so by fusing the concept of data wit the intuitive and rich semantics of graphs as the lowest level primitive to view memory.

> **Nerd Alert 2** *(time to let your eyes glaze over)*
>
> A context is a representation of data that can be expressed simply as a 3-tuple $(\sum_K, \sum_V, p_K)$, where
>
> 1. $\sum_K$ is a finite alphabet of keys
>
> 2. $\sum_V$ is a finite alphabet of values
>
> 3. p_K is the pairing of keys to values

Getting Jac'd: T

Chapter 6

The Jac Programming Language

To articulate the sourcer spells made possible by the wand that is Jaseci, I bestow upon thee, the Jac programming language. (Like the Harry Potter [5] simile there? Cool, I know ;-))

The name Jac take was chosen for a few reasons.

- "Jac" is three characters long, so its well suited for the file name extention `.jac` for Jac programs.

- It pulls its letters from the phrase **JA**seci **C**ode.

- And it sounds oh so sweet to say "Did you grok that sick Jac code yet!" Rolls right off the tongue.

This chapter provides the full deep dive into the language. By the end, you will be fully empowerd with Jaseci wizardry and get a view into the key insights and novelty in the coding style.

6.1   Getting the Basics Out of the Way

First lets quickly dispense with the mundane. This section covers the standard table stakes fodder present in pretty much all languages. This stuff must be included for completeness, however you should be able to speed read this section. If you are unable to speed read this, perhaps you should give visual basic a try.

Figure 6.1: World's youngest coder with valid HTML on shirt.[1]

6.1.1   The Obligatory Hello World

Let's begin with what has become the unofficial official starting point for any introduction to a new language, the "hello world" program. Thank you Canada for providing one of the most impactful contributions in computer science with "hello world" becaming a meme both technically and socially. We have such love for this contribution we even tag or newborns with the phrase as per Fig. 6.1. I digress. Lets now christen our baby, Jaseci, with its "Hello World" expression.

```
Jac Code 6.1:  Jaseci says Hello!
1  walker init {
2      std.out("Hello World");
3  }
```

Simple enough right? Well let's walk through it. What we have here is a valid Jac program with a single walker defined. Remember a walker is our little robot friend that walks the nodes and edges of a graph and does stuff. In the curly braces, we articulate what our walker should do. Here we instruct our walker to utilize the standard library to call a print function denoted as `std.out` to print a single string, our star and esteemed string, "Hello World." The output to the screen (or wherever the OS is routing it's standard stream output) is simply,

```
1  Hello World
```

---

[1]Image credit to wiki contributer [1]

And there we have the most useless program in the world. Though. . . technically this program is AI. Its not as intelligent as the machine depicted in Figure 6.1, but one that we can understand much better (unless you speak "goo goo gaa gaa" of course). Let's move on.

6.1.2 Basic Arithmetic Operations

Next we should cover the he simplest math operations in Jac. We build upon what we've learned so far with our conversational AI above.

```
Jac Code 6.2: Basic arithmetic operations
walker init {
    a = 4 + 4;
    b = 4 * -5;
    c = 4 / 4; # Evaluates to a floating point number
    d = 4 - 6;
    e = a + b + c + d;
    std.out(a, b, c, d, e);
}
```

The output of this groundbreaking program is,

```
8 -20 1.0 -2 -13.0
```

Jac Code 6.2 is comprised of basic math operations. The semantics of these experisions are pretty much the same as anything you may have seen before, and pretty much match the semantics we have in the Python language. In this Example, we also observe that Jac is an untyped langauge and variables can be delcared via a direct assignment; also very Python'y. The comma separated list of the defined variables `a` - `e` in the call to `std.out` illustrate multiple values being printed to screen from a single call.

Additionally, Jac supports power and modulo operations.

```
Jac Code 6.3: Additional arithmetic operations
walker init {
    a = 4 ^ 4; b = 9 % 5; std.out(a, b);
}
```

Jac Code 6.3 outputs,

```
256 4
```

Here, we can also observe that, unlike Python, whitespace does not mater whatsoever. Languages utilizing whitespace to express static scoping should be criminalized. Yeah, I

said it, see Rant A.2. Anyway, A corollary to this design decision is that every statement must end with a ";". The wonderful ;, A nod of respect goes to `C/C++/JavaScript` for bringing this beautiful code punctuation to the masses. Of course the ; as code punctuation was first introduced with `ALGOL 58`, but who the heck knows that language. It sounds like some kind of plant species. Bleh. Onwards.

Nerd Alert 3 *(time to let your eyes glaze over)*

Grammar 6.4 shows the lines from the formal grammar for Jac that corresponds to the parsing of arithmetic.

```
Grammar 6.4:  Jac grammar clip relevant to arithmetic
126  arithmetic: term ((PLUS | MINUS) term)*;
127
128  term: factor ((MUL | DIV | MOD) factor)*;
129
130  factor: (PLUS | MINUS) factor | power;
131
132  power: func_call (POW factor)* | func_call index+;
```

(full grammar in Appendix B)

6.1.3   Comparison, Logical, and Membership Operations

Next we review the comparison and logical operations supported in Jac. This is relatively straight forward if you've programmed before. Let's summarize quickly for completeness.

```
Jac Code 6.5:  Comparision operations
1   walker init {
2      a = 5; b = 6;
3      std.out(a == b,
4              a != b,
5              a < b,
6              a > b,
7              a <= b,
8              a >= b,
9              a == b-1);
10  }
```

```
1   false true true false true false true
```

In order of appearnce, we have tests for equality, non equality, less than, greater than, less than or equal, and greater than or equal. These tools prove indispensible when expressing functionality through conditionals and loops. Additionally,

```
Jac Code 6.6:  Logical operations
1  walker init {
2      a = true; b = false;
3      std.out(a,
4              !a,
5              a && b,
6              a || b,
7              a and b,
8              a or b,
9              !a or b,
10             !(a and b));
11 }
```

```
1  true false false true false true false true
```

Jac Code 6.6 presents the logical operations supported by Jac. In oder of appearnce we have, boolean complement, logical and, logical or, another way to express and and or (thank you Python) and some combinations. These are also indispensible when using conditionals.

[NEED EXAMPLE FOR MEMBERSHIP OPERATIONS]

Nerd Alert 4 *(time to let your eyes glaze over)*

Grammar 6.7 shows the lines from the formal grammar for Jac that corresponds to the parsing of comparison, logical, and membership operations.

```
Grammar 6.7:  Jac grammar clip relevant to comparison, logic, and membership
116  logical: compare ((KW_AND | KW_OR) compare)*;
117
118  compare:
119          NOT compare
120          | arithmetic (
121                  (EE | LT | GT | LTE | GTE | NE | KW_IN | nin) arithmetic
122          )*;
123
124  nin: NOT KW_IN;
```

(full grammar in Appendix B)

6.1.4 Assignment Operations

Next, lets take a look at assingment in Jac. In contrast to equality tests of ==, assignment operations copy the value of the right hand side of the assignment to the variable or object on the left hand side.

```
Jac Code 6.8:   Assignment operations
```
```
1   walker init {
2       a = 4 + 4; std.out(a);
3       a += 4 + 4; std.out(a);
4       a -= 4 * -5; std.out(a);
5       a *= 4 / 4; std.out(a);
6       a /= 4 - 6; std.out(a);
7
8       # a := here; std.out(a);
9       # Noting existence of copy assign, described later
10  }
```

```
1   8
2   16
3   36
4   36.0
5   -18.0
```

As shown in Jac Code 6.8, there are a number of ways we can articulate an assinment. Of course we can simply set a variable equal to a particular value, however, we can go beyond that to set that assinment relative to its original value. In particular, we can use the short hand `a += 4 + 4;` to represent `a = a + 4 + 4;`. We will describe later an additional assignment type we call the copy assign. If you're simply dying of curiousity, I'll throw you a bone. This `:=` assignment only applies to nodes and edges and has the semantic of copying the member values of a node or edge as opposed to the particular node or edge a variable is pointing to. In a nutshell this assignment uses pass by value semantics vs pass by reference semantics which is default for nodes and edges.

> **Nerd Alert 5** *(time to let your eyes glaze over)*
>
> Grammar 6.9 shows the lines from the formal grammar for Jac that corresponds to the parsing of assignment operations.
>
> ```
> Grammar 6.9:   Jac grammar clip relevant to assignment

Table 6.1: Precedence of operations in Jac

6.1.5   Precedence in Jac

At this point in our discussion its important to note the precedence of opperations in Jac. Table 6.1 summarizes this precedence. There are a number of new and perhaps interesting things that appear in this table that you may not have seen before. [JOKE] For now, don't hurt yourself trying to understand what they are and mean, we'll get there.

6.1.6   Foreshadowing Unique Graph Operations

Before we move on to more mundane basics that will continue to neutralize any kind of caffine or methamphetamine buzz an experienced coder might have as they read this, lets enjoy a Jaseci jolt!

Figure 6.2: Graph in memory for simple Hello World program (JC 6.1)

As described before, all data in Jaseci lives in either a graph, or within the scope of a walker. A walker, executes when it is *engaged* to the graph, meaning it is located on a particalar node of the graph. In the case of the Jac programs we've looked at so far, each progam has specified one walker for which I've happend to choose the name `init`. By default these init walkers are invoked from the default root node of an empty graph. Figure 6.2 shows the complete state of memory for all of the Jac programs discussed thus far. The `init` walker in these cases does not *walk* anywhere and has only executed a set of operations on this default root node `n0`.
Let's have a quick peek at some slick language syntax for building this graph and traveling to new nodes.

```
Jac Code 6.10:  Preview of graph operators
1  node simple;
```

```
2  edge back;
3
4  walker kewl_graph_creator {
5      node_a = spawn here --> node::simple;
6      here <-[back]- node_a;
7      node_b = spawn here <--> node::simple;
8      node_b --> node_a;
9  }
```

Jac Code 6.10 presents a sequence of operations that creates
nodes and edges and produces a relatively simple complex
graph. There is a bunch of new syntactic goodness presented
in less than 10 lines of code and I certainly won't describe them
all here. The goal is to simply whet your appitite on whats to
come. But lets look at the state of our data (memory) shown
in Figure 6.3.

Yep, there a good bit going on here. in less than 10 lines of
code we've done the following things:

1. Specified a new type of node we call a simple node.

2. Specified a new type of edge we call a back edge.

3. Specified a walker kewl_graph_creator and its behavior

4. Instantiated a outward pointing edge from the n0:root node.

5. Instantiated an instance of node type simple

6. Connected edge from from root to n1

7. Instantiated a back edge

8. Connected back edge from n1 to n0

9. Instantiated another instance of node type simple, n2

10. Instantiated an undirected edge from the n0:root node.

11. Connected edge from root to n2

12. Instntiated an outward pointing edge from n2
13. Connected edge from n2 to n1

Figure 6.3: Graph in memory
for JC 6.10

Don't worry, I'll wait till that sinks in. . . Good? Well, if you liked that, just you wait.

This is going to get very interesting indeed, but first, on to more standard stuff. . .

Part III

Crafting Jaseci

Chapter 7

Architecting Jaseci Core

Chapter 8

Architecting Jaseci Cloud Serving

Epilogue

Appendix A

Rants

A.1   Libraries Suck

Because they do.

Still need more reasons?

Well, if you dont already know, I'm not going to tell you.

. . .

Still there?

. . .

Fine, I'll tell you.

1. They suck because they create dependancies for which you must have faith in the implementer of the library to maintain and keep bug free.

2. They suck because there are often at least 10 options to choose from with near exact features expressings slightly different idosyncratic ways.

3. They suck because they suck.

Don't get me wrong, we have to use libraries. I'm not saying go reimplement the wheel 15 thousand times over. But that doesn't mean they don't suck and should be avoided

if possible. The best is to know your library inside and out so the moment you hit some suckitude you can pull in the library's source code into your own codebase and pwn it as your own.

A.2   Utilizing Whitespace for Scoping is Criminal (Yea, I'm looking at you Python)

This whitespace debautchery perpetrated by Python and the like is one of the most perverted abuses of ASCII code 32 I've seen in computer science. It's an assult on the freedom of coders to decide the shape and structure of the beautiful sculptures their creative minds might want to actualize in syntax. Coder's fingers have a voice! And that voice deserves to be heard! The only folks that support this oppression are those in the 1% that get paid on a per line of code basis so they can lean on these whitespace mandates to pump up their salaries at the cost of coders everywhere.
